Abstract

3-diregular circulant digraph on 12 vertices is a counterexample of Jackson's conjecture about hamiltonicity of diregular digraphs

Conjecture 1 (Jackson [1] p. 68, 5.42)**.** Every k-diregular oriented graph on at most $4k+1$ vertices where $k \neq 2$ contains a directed Hamiltonian circuit.

Jackson's bound is best possible because of the disjoint union of two k-diregular tournaments on $2k+1$ vertices.

Claim 1.1. *Counterexample*

Computer search for non-hamiltonian circulant digraphs found the following counterexample.

Let H be the circulant digraph on 12 veritces $\{0,1,2\dots 11\}$ and edges i is adjacent to $\{i+2 \mod 12, i+3 \mod 12, i+8 \mod 12\}$.

Proof. By construction and inspection it is 3-diregular and oriented.

Non-hamiltonicity was noted by results of the CAS sage [2] and since the digraph is small exhaustive search with [2] confirmed it is non-hamiltonian.

From discussion we learned H appears in [3] as $\mathrm{Cay}(\mathbb{Z}_{12}; 2, 3, 8)$ on p. 2. Non-hamiltonicity is proved in [3] p. 6 Theorem 4.6. The second non-hamiltonian circulant digraph on 12 vertices in [3] is not oriented.

H is on 12 vertices, less than the bound $4 \cdot 3 + 1 = 13$ so satisfies the hypotheses for Jackson's conjecture, and not the conclusion. H is counterexample to a weaker conjecture with $4k+1$ replaced by $4k$.

Computer search for circulant counterexamples didn't find others on less than 21 vertices.

By coincidence $\mathrm{Cay}(\mathbb{Z}_{12}; 2, 3, 8)$ is a counterexample to Adam's conjecture as shown in [4]. □
